Lab Exercises 9 – JavaScript (Form Validation)

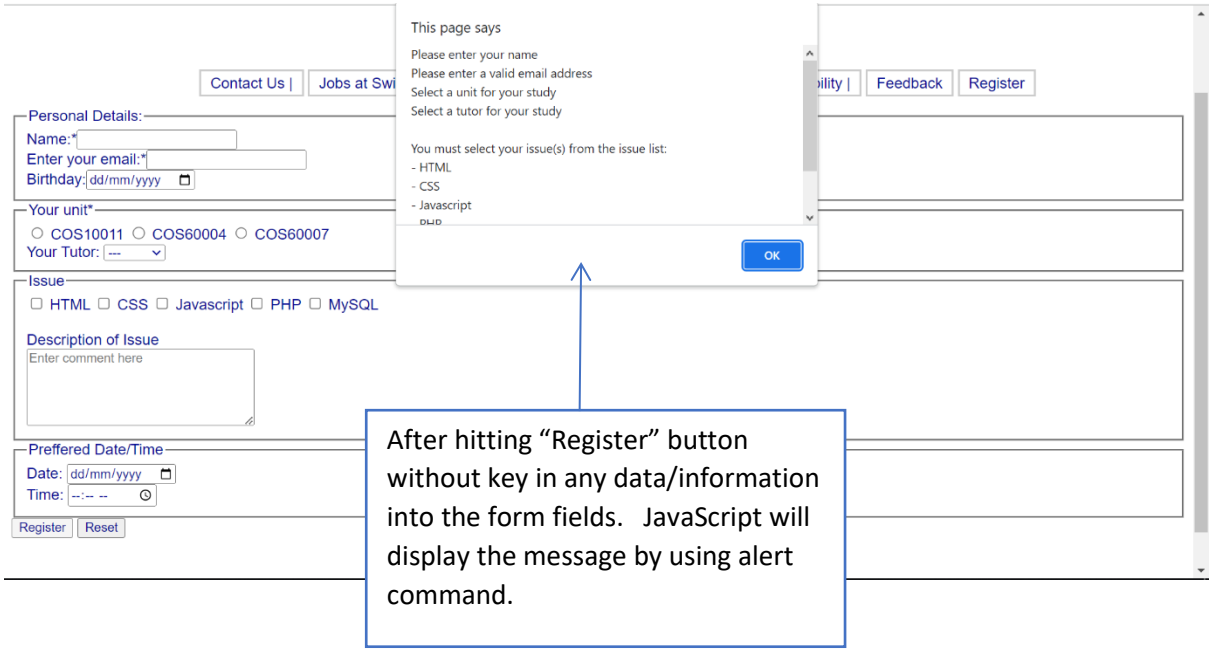

Aims

- To practice how to create a form data checking/validation function for a HTML form using JavaScript while maintaining clear separation of HTML, CSS and JS file.
- To review JavaScript functions and control structure.
- To gain the skills and knowledge to complete Assignment 2.

Task 1: Create Form validation using JavaScript

Again we are going to start with a registration form, then define and add a client-side form data validation function using JavaScript. In this lab, we will be using the JavaScript alert function to display the error message.

Output should look as below:

After hitting "Register" button without key in any data/information into the form fields. JavaScript will display the message by using alert command.

Step 1: Form Design (HTML and CSS)

- Use notepad++ to open and edit register.html. Review the HTML and locate the 'comments' where will add missing code.
- Format the register.html code based on the instructions below:

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <meta charset="UTF-8"/>
    <meta name="description" content="Swinburne Website"/>
    <meta name="keywords" content="Studying at Swinburne University"/>
    <meta name="author" content="xxx"/>
    <meta name="viewport" content="width=device-width, initial-scale=1.0"/>
    <!-- 1 -->
    <!-- 2 -->
    <title>Swinburne Website</title>
  </head>
  <body>
    <header>
        <img id="images" src="SwinLogo.png" alt="Swinburne Logo"/>
    </header>
    <nav>
```

1) Link style.css from style folder to register.html using <link>.
2) Link validate JavaScript to register.html using <script></script>.
3) Format <meta name= "author" content= "***to your name***">

```
    </ul>
</nav>
<form id="detail" method="post" action="#" novalidate="novalidate">
    <fieldset>
        <legend>Personal Details:</legend>
            <label for="name">Name:*</label><input type="text" id="name" name=
            <br/>
            <label for="email">Enter your email:*</label><input type="email" i
            <br/>
            <label for="birthday">Birthday:</label><input type="date" id="birt
            <br/>
    </fieldset>
```

4) Insert your email address into action= " ".

```
            <legend>Preffered Date/Time</legend>
            <label for="date">Date:</label>
            <input type="date" id="date" name="date" value=""/><br/>
            <label for="time">Time:</label>
            <input type="time" id="time" name="time"/>
        </fieldset>
        <input type="submit" value="Register" />
        <input type="reset" value="Reset" />
    </form>
    <footer>
    <p>Posted by: xxx</p>
    <p>Contact information: <a href="mailto:abc@gmail.com">xxx</a></p>
    </footer>
  </body>
</html>
```

5) Lastly Insert your name and your own email address for footer.

Step 2: JavaScript Creation (for the Form Validation)

Use notepad++ to create validate.js. You may follow the demo from the lecture to complete this task.

1. Create an initial function to kick start the validation process. This function is to get the element from the form register.html. By using onsubmit command to activate (call) the validate function later.
2. Do not forget the global variable to store the error message(s).
3. A validateForm function is created to call each individual checking based on the following rules:
    - Name cannot be empty and must contain alpha characters.
    - Email cannot be empty and must be a valid email address (check for "@").
    - Unit and tutor have to be selected.
    - Must select one of the issues.
    - Description cannot be empty.
4. If the user misses out on any values after clicking the Register button, it should display an alert message with appropriate error message to clearly indicate the input error. For example:
